

Applications of Multi-Node Optical Splitters

Overview

By dividing a single optical signal from a central Optical Line Terminal (OLT) into multiple outputs for Optical Network Terminals (ONTs) at users' homes, splitters eliminate the need for dedicated fibers to each residence—slashing infrastructure costs while scaling network reach. Splitters are passive optical devices that divide or combine optical signals, and they come in various types, including power splitters, uneven splitters, and wavelength-division multiplexing (WDM) splitters. Each type serves specific applications, enabling efficient use of optical infrastructure. A “splitter” is a power splitter. Light power goes in and light power coming out. Fiber optic splitters are essential passive devices in modern optical communication systems, enabling the division of a single light signal into multiple outputs or combining multiple signals into one.
