

Can cold-joints be heat-fused

Overview

In heat fusion joining, mating surfaces are prepared and simultaneously melted with a hot-plate heater. As the molten materials cool, they mix and fuse into a permanent . A hot joint refers to a connection made through the application of heat or thermal energy, typically involving processes such as welding, soldering, or brazing, where the base materials are heated to create a permanent bond through molecular fusion or the introduction of a molten filler material. Additionally, there are two methods for producing the socket and saddle fusion joints. In addition to the fusion procedures that follow, electrofusion is recognized as an acceptable method of. There are three types of conventional heat fusion joints currently used in the industry; Butt, Saddle, and Socket Fusion. 1 The procedures described in Sections 7 – 9 are primarily intended for (but not limited to) field joining of polyethylene (PE) pipe and fittings, using suitable equipment and appropriate environmental control procedures. When properly implemented, strong pressure/leak-tight joints are produced.
