

Distribution Box Simulation System

Overview

Materials behave differently in compression than they do in tension. Depending on the specific application, it can be important to perform mechanical tests which simulate these forces the material will experience in actual use. Compression strength testing is typically used to test materials such as plastics, elastomers, rubber, composites, foam, etc. Through the utilization of tests simulating the shocks and stresses normally encountered during handling and transportation. ISTA tests provide a means for a manufacturer to assign the probability of safe arrival for their packaged products. Sample Size - The optimum sample size is ten (10) shipping units with the primary packages assembled as intended. Pallets are important to many industries, as most products are shipped on a pallet at some point in the manufacturing and sales process. If a pallet fails to provide a safe and stable platform, packaged products may be damaged, resulting in added costs. DDL tests pallets to make sure that they can hold and support full unit loads of products through.
