

Electrical signals output by the optical module

Overview

When the optical signals reach the receive optical bore through an optical fiber, they are converted back into electrical signals by the photodetector diode. The electrical signals are then output at the corresponding bit rate after passing the preamplifier. An optical module works at the physical layer of the OSI model and is one of the core components in the fiber communication. Subsequently, the driver semiconductor laser (LD) or light-emitting diode (LED) emits modulated optical signals at the corresponding rate. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside. The optical module serves as a crucial component in optical fiber communication systems, operating at the physical layer, which is the lowest layer in the OSI model. These compact yet powerful devices serve as the bridge between electrical.
