

Grounding requirements for optical cable shielding layer

Overview

Meeting standards like ANSI/TIA-607-D and ISO/IEC 11801 requires proper grounding of shielded systems. Without effective grounding, these shields can inadvertently act as antennas, attracting EMI rather than deflecting it. It's important to recognize the different shielding. This Applications Engineering Note (AE Note) discusses conventional bonding and grounding practices for conductive fiber optic cable and hardware installations within the scope of the National Electrical Code (NEC). Signal integrity preserved: With one grounding point, the balanced design of twisted pairs works as intended, minimizing interference and keeping data. A shielded cable or a cable with a metal jacket is recommended for the signal cable that is routed in to or out from a site. No practical shield provides magnetic-field protection at low frequency. Generally, cables fall into two broad categories: power cables, which transmit electrical power at relatively high voltages and currents, and signal cables, which carry low-level signals.
