Holding the fuse in long nosed pliers with rubber bands and perhaps blue-tack acting as a heat absorbers and keeping the pliers locked on the fuse, it is easy to apply enough heat to the CB contact and each end of the fuse to avoid a cold weld but get a strong. The fuses to be considered are current-sensitive devices which are designed as the intentional weak link in the electrical circuit. The function of a fuse is to provide discrete component or complete circuit protection by reliably melting under overcurrent conditions and thus safely interrupting. DERIVATION OF NOMINAL MELTING I²t: Laboratory tests are conducted on each fuse design to determine the amount of energy required to melt the fusing element. This energy is described as nominal melting I²t and is expressed as "Ampere Squared Seconds" (A² Sec. A pulse of current is applied to the. Fuses are current-sensitive devices that provide reliable protection for systems, components, or circuits by melting under current overload conditions. by holding them with a wet cloth). My suggestion, given your lack of space is to attach with conductive silver epoxy. Someone has suggested somewhere to add a thermal fuse to the build, in case the fan fails, the heater might heat up very quickly and thermal fuse will protect from over heating and potential fire. It interrupts a circuit when an over-current condition, such as an overload or short-circuit, occurs.
