

Overfrequency protection principle of relay protection

Overview

Over frequency protection is configured by applying a set point above normal operating frequency. The frequency in electrical installations must be maintained within accepted operating levels to minimize the risk of damage to motor loads, sensitive electronics, and to ensure the proper operation and performance of all loads. There are two independent protections: Under/overfrequency protection. Over frequency protection or over speed protection is used to protect the generator from over speeding of generator's rotor, reduce the eddy current losses as the frequency increases and protect the winding against v/f over fluxing protection. Normally, Generator is an energy conversion device. Protective relays and devices have been developed over 100 years ago to provide “lastline” of defense for the electrical systems. In this article, we explore what normal frequency is, what scenarios cause power system frequency to vary, and some of the common protection elements which act on these fault scenarios.
