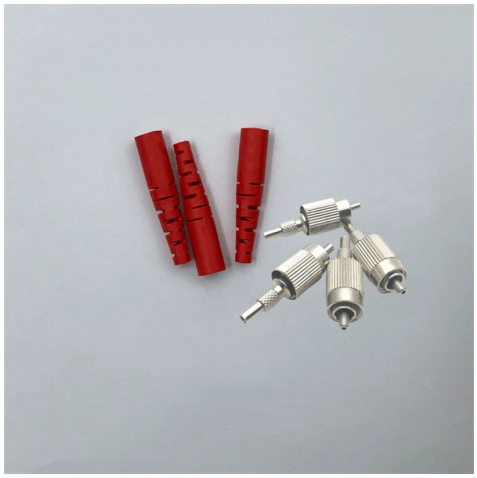
PCM fiber optic or cable channel



Overview

We'll then compare how optical and coaxial cables transmit PCM signals—optical cables use light pulses through fiber optics, making them resistant to electrical interference, while coaxial cables rely on electrical pulses through copper wires, which can be more. We'll then compare how optical and coaxial cables transmit PCM signals—optical cables use light pulses through fiber optics, making them resistant to electrical interference, while coaxial cables rely on electrical pulses through copper wires, which can be more. These ports are called “outs” because they are specifically used to put out video or sound. Some digital audio devices can be used to send signals while others only take in signals, such as microphones. To get sound from a digital audio output, you would use an optical or coaxial cable to connect. We'll start by defining PCM (Pulse Code Modulation) and how it converts analog sound into digital data that your audio equipment can process. We'll then compare. TOSLINK (Toshiba Link) is a standardized optical fiber connector system. Generically known as optical audio, the most common use of the TOSLINK optical fiber connector is in consumer audio equipment in which the digital optical socket carries (transmits) a stream of digital audio. Fibre Channel (FC) is a high-speed network protocol designed for transferring large volumes of data between servers and storage devices, typically within a Storage Area Network (SAN). Fibre Channel. PCM over optical is limited to 2 channels however bitstream (with limitations) is also supported which means DTS and Dolby Digital will also work over optical however optical has a bandwidth limitation which means you won't get DTS-HD, Dolby Digital+ or Dolby Atmos.
