

SNMP Configuration on the Core Switch

Overview

Consider the Community String as the password that must be used between the SNMP server and the networking device (e.g Cisco router, switch, firewall etc) in order to allow each other to communicate. It is analogous to an API key that you must have in order to communicate with an API end-point. The community string is configured on both the network. Currently there are 3 SNMP versions as below:

1. SNMP v1: This is the original version which uses community strings to communicate. This version has critical performance limitations and should be avoided.
2. SNMP v2c: This is an upgraded version from v1 but still uses the same community strings communication method. However, it has several performance improvements. You need to know the correct port numbers used by the SNMP protocol in order to open them on your firewall for proper device monitoring by the SNMP manager. Basically you need to open the following ports between the agents (devices) and the manager (snmp server):

1. Port 161 (UDP): This is the standard port for SNMP agents to receive requests from S.
