

The PIC in the optical module

Overview

A photonic integrated circuit (PIC) or integrated optical circuit is a microchip containing two or more photonic components that form a functioning circuit. This technology detects, generates, transports, and processes light. Although optical signals do not propagate faster than electrical signals in typical interconnect media, photonics. The PIC100 is ST's first silicon photonics technology and one of the most efficient PICs on a 300 mm wafer, thus enabling 200Gbps/lane and even greater bandwidth in the future. Indeed, this is a highly symbolic launch as it inaugurates a long series of PICs that will bring new efficiencies to data. This is a continuation from the previous tutorial - optical amplifiers. During the 1980s and early 1990s, there has been a significant number of developments in the technology of optical and electronic integration of semiconductor lasers and other related devices on a single chip. Increased complexity in chip functionality has resulted in a need for increased fabrication complexity from III-V epitaxy, through wafer.
