

Zero-sequence current appears in relay protection

Overview

Zero sequence current analysis is widely used in power system protection, particularly in ground fault detection schemes such as residual current protection and earth fault relays, where the presence of this current indicates leakage or fault conditions in the network. In a balanced three-phase system, the vector sum of phase currents is zero, so no zero-sequence current exists. Positive sequence current represents the normal operating condition. ✓ Always flows through transformer ✓ Independent of winding configuration ✓ Equal to transformer leakage impedance This is the current responsible for normal power transfer. $I_2 = 3I_1$ (I a . Abstract—Modern relays provide protection elements that were historically not used due to cost or panel space restrictions. These new elements can provide improved protection for the power system. However, protection engineers may be unfamiliar with the behavior of these elements and may make. In relay protection systems, we often encounter concepts such as zero-sequence current protection in microprocessor-based protection relay and inverse-time negative-sequence protection in transformer protection relays.
